ABSTRACT

This study aimed to evaluate the effects of systemic melatonin on wound healing after tooth extraction. This study was conducted on twenty healthy adult male New Zealand albino rabbits. Tooth extraction was done on all rabbits, and then animals were divided into two major groups. Control group (n=10): received no treatment. Melatonin treated group (n=10): received melatonin orally (1mg/kg) dissolved in distilled water; gave it to the rabbits once daily for a determined period. On days seventh and fourteenth, all animals in each group were sacrificed. The wound area site undergoes histological examination to compare the healing among the control group and melatonin treated group. The present study demonstrated that melatonin treated group found to accelerate wound healing manifested by a score of angiogenesis (1.6 ± 0.54), granulation tissue (2 ± 0.70) and reepithelization (1.2 ± 0.44) while a decrease in inflammatory cells (0 ± 0.00) in comparison to control group at 7th and (2 ± 0.70), (2.2 ± 0.44), (2.6 ± 0.54) respectively and decrease in inflammation (0 ± 0.00) at the 14th day. In this study, we found that systemic melatonin accelerates socket wound healing after tooth extraction.

INTRODUCTION

Tooth extraction initiates a series of reparative processes including both hard tissue (i.e., alveolar bone) and soft tissues (periodontal ligament, gingiva) (Farina and Trombelli, 2011). Several alterations occur after tooth extraction, both histologically and clinically. A blood clot forms then are replaced by granulation tissue, which is then replaced by mineralized, immature, woven bone in the first 6–8 weeks following an extraction. However, bone remodeling will yield mature bone in the next 16–18 weeks, with little consistency among patients. In fact, in some patients, the process of bone remodeling may not be finished by the end of these 24 weeks (Kulkareni *et al.*, 2019).

Accelerate wound healing after a tooth extraction is helpful in dental treatment (Khoswanto, 2019). The use of antioxidants such as melatonin may support wound healing after tooth extraction (Sharafati-Chaleshtori *et al.*, 2017). Lerner *et al.*, (1958) discovered melatonin (Nacetyl5methoxy-tryptamine), an indoleamine, in the bovine pineal gland in 1958 (De Rensis *et al.*, 2020). It's a pineal gland-produced circadian endocrine molecule that was first

identified as a factor in regulating physiological systems and processes, including circadian rhythms, Immune system, cardiovascular system, reproduction, hormone secretion, accelerates wound healing and aging process (Hardeland, 2017).

Exogenous melatonin has hypnotic/sedative effects, improves angiogenesis phases of wound healing, counteracts immune deficiencies, changes the timing of fatigue and sleep, acts as an acute sleepiness-inducing, and affects circadian rhythms and general health. (Barriga *et al.*, 2001). A recent study found that melatonin ameliorates autistic-like behavior induced in pups of rats (Taqa *et al.*, 2021). Melatonin is said to have both receptor-mediated and receptor-independent effects (for example, radical scavenging) actions (Imenshahidi *et al.*, 2020). Therefore, this study aims to evaluate melatonin's clinical and histological effect on socket wound healing after tooth extraction.

MATERIALS AND METHODS

The research was conducted at the Department of Dental Basic Science, College of Dentistry, University of Mosul, Iraq.

Animals:

Twenty healthy adult male white albino rabbits with a weight range from (1.5- 2.5) Kg, aged (5-6) months used in this study. The animals were housed in normal conditions, including *ad libitum* feeding (wheat and fresh vegetables), housing at (25) °C room temperature, and a 12-hour lighting and 12-hour darkening system (Ayranci *et al.*, 2016). The animal was held in a cage at the University of Mosul's College of dentistry's animal house . A veterinarian examined the animals to determine their general health and condition prior to surgical procedure.

Surgical procedure:

Ketamine hydrochloride (40 mg/kg) and xylazine (5 mg/kg) injections were administered intramuscularly to anesthetize the rabbits (Salduz *et al.*, 2017) within 5 minutes, complete anesthesia had been achieved. The animals were put in a left lateral position on the operation table, and the left central incisor was separated from the upper jaw using a standardized sterile procedure.

Experimental Protocol:

This study was conducted on twenty healthy adult male New Zealand albino rabbits. Tooth extraction was done on all rabbits (Fig. 1, A and B) and then animals were divided into two major groups. Control group (n=10): received no treatment. Melatonin treated group (n=10): received melatonin (1mg/kg) systemically gave it by mouth once time daily for a determined period time (Fig.2, A and B). On days seventh and fourteenth, all animals in each group were sacrificed and underwent histological examinations. The area of socket wound site was performed to compare the healing of the control and melatonin-treated groups.

Fig.1: A: Picture of the anesthetized rabbit .B: Rabbits Tooth after extraction.

Post-Operative Care:

Immediately after the procedure, the rabbits were separated until they recovered from anesthesia. Observation of the feeding and physical activity of the operated animals during the first 24 hours after surgery.

Fig.2: A: On the seventh day of treatment. B: On the fourteenth day of treatment.

Histopathopathological examination:

On the 7th and 14th day of treatment, all animals were sacrificed for histopathological examination of the oral mucosal wound of the socket. The tissue was fixed, processed and stained by Hematoxylin and Eosin, then examined under a light microscope, and the criteria of histopathological examination were according to (Gupta and Kumar, 2015; Lucaciou *et al.*, 2015; Salim and Munawah, 2020)

Statistical analysis:

The data were expressed as mean $\pm$ SD, and the variance between two experimental sets was statistically analyzed using Non-parametric analysis and a two-sample Mann-Whitney U test. The significance threshold was set at $P < 0.05$ (Ali and Bhaskar, 2016).

RESULTS

On day 7: Control group:

The microscopic investigation of histological slides representing by peripherally present newly blood vessels (angiogenesis), the histopathological score's mean value was (1.4 $\pm$ 0.54), scanty amount of granulation tissue, the mean value of histopathological score was (1.6 $\pm$ 0.54), and inflammatory infiltration the histopathological score's mean value was, (1.8 $\pm$ 0.83) without reepithelialization the mean value of histopathological score was (0 $\pm$ 0.0) (Table 1 ; Fig. 3, 4).

Table 1: Histopathological Finding of Socket wound healing that treated systemically. (Mean $\pm$ standard deviation) on day 7.

Day 7	Inflammation	Angiogenesis	Granulation	Reepithelialization
Control	1.8 $\pm$ 0.83	1.4 $\pm$ 0.54	1.6 $\pm$ 0.54	0.0 $\pm$ 0.0
Melatonin	0 $\pm$ 0.00	1.6 $\pm$ 0.54	2.0 $\pm$ 0.70	1.2 $\pm$ 0.44
P-value	0.005	0.55	0.339	0.004

Histological and clinical finding of systemic melatonin on wound healing.....

Fig. 3: Mean rank differences between control and systemically melatonin treated groups on the 7th day of healing for inflammation, Angiogenesis, Granulation and Reepithelization.

Group treated with melatonin systemically:

The microscopic investigation of histological slides shows the site of wound represented by peripherally present newly blood vessels (angiogenesis), the mean value of histopathological score (1.6 ± 0.54), moderate amount of granulation tissue, the mean value of histopathological score was (2 ± 0.70), without inflammatory infiltration, the histopathological score's mean value was (0 ± 0.00) and reepithelialization below the half of the wound, the mean value of histopathological score was (1.2 ± 0.44) (Table 1; Figs. 3 and 4).

Fig. 4: Seven day period of the histopathological section of the tooth socket:

A: photomicrograph of socket wound of control group shows (A) representing by the scanty amount of granulation tissue (score 1) (B), peripherally present newly blood vessels (angiogenesis) (score 1), (C), and inflammatory infiltration (score 1) without reepithelialization (score 0) (D). 100X.

B: photomicrograph of socket wound of control gp representing by (A) scanty amount of granulation tissue (score 1) (B), peripherally present newly blood vessels (angiogenesis) (score 1), (C), and inflammatory infiltration (score 1) without reepithelialization (score 0) (D), 400X.

C: photomicrograph of socket wound of melatonin group (A) representing by a moderate amount of granulation tissue (score 2) (B), peripherally present newly blood vessels (angiogenesis) (score 1), (C), without inflammatory infiltration (score 0) and reepithelialization below the half of the wound (score 1) (D). 100X.

D: photomicrograph of socket wound of melatonin group (A) representing by a moderate amount of granulation tissue (score 2) (B), peripherally present newly blood vessels (angiogenesis) (score 1), (C), without inflammatory infiltration (score 0) and reepithelialization below the half of the wound (score 1) (D). 400X.

On Two independent Sample (Mann Whitney U), the Statistical test showed that the mean of the melatonin-treated group is higher than that of the control group for inflammation and reepithelization. P-value was less than 0.05, which indicates a significant difference in inflammation and reepithelization between the two groups. In contrast, the P-value of angiogenesis and granulation was more than 0.05, showing a non-significant difference between melatonin and the control group.

On day 14 :

Control group:

Photomicrograph of socket wound of control group shows the site of wound representing by peripherally present newly blood vessels (angiogenesis), the histopathological score's mean value was (1.6 ± 0.54), scanty amount of granulation tissue, the mean value of histopathological score was (1.4 ± 0.54), inflammatory infiltration, the histopathological score's mean value was (1.4 ± 0.54) and reepithelialization below the half of the wound, the mean value of histopathological score was (1.2 ± 0.44).

Melatonin treated group (Systemically):

Photomicrograph of socket wound of melatonin group shows the site of wound representing by peripherally and centrally present newly blood vessels (angiogenesis), the mean value of histopathological score was (2 ± 0.70), a moderate amount of granulation tissue, the histopathological score's mean value was (2.2 ± 0.44), (C), without inflammatory infiltration, the mean value of histopathological score was (0 ± 0.0) and irregular full thickness of reepithelialization of the wound is the histopathological score's mean value was (2.6 ± 0.54) (Table 2; Figure 5 and 6).

Table2: Histopathological Finding of Socket wound healing that treated systemically at 14th day (mean $\pm$ standard deviation).

Day 14	Inflammation	Angiogenesis	Granulation tissue	Reepithelization
Control	1.4 ± 0.54	1.6 ± 0.54	1.4 ± 0.54	1.2 ± 0.44
Melatonin	0.0 ± 0.00	2.00 ± 0.70	2.2 ± 0.44	2.6 ± 0.54
P-value	0.005	0.339	0.042	0.011

Fig. 5: Mean rank differences between control and systemically melatonin treated groups on the 14th day of healing for inflammation, Angiogenesis, Granulation and Reepithelization.

Fig. 6: Fourteenth day period of the histopathological section of the tooth socket.

A: photomicrograph of socket wound of the control group (A) representing by the scanty amount of granulation tissue (score 1) (B), peripherally present newly blood vessels (angiogenesis) (score 1), (C), inflammatory infiltration (score 1) and reepithelialization below the half of the wound (score 1) (D) 100X.

B: photomicrograph of socket wound of the control group (A) representing by the scanty amount of granulation tissue (score 1) (B), peripherally present newly blood vessels (angiogenesis) (score 1), (C), inflammatory infiltration (score 1) and reepithelialization below the half of the wound (score 1) (D) 400X.

C: photomicrograph of socket wound of treated group (A) representing by a moderate amount of granulation tissue (score 2) (B), peripherally and centrally present newly blood vessels (angiogenesis) (score 2), (C), without inflammatory infiltration (score 0) and irregular full thickness of reepithelialization of the wound area (score 3) (D).100X.

D: photomicrograph of skin wound of melatonin group (A) representing by a moderate amount of granulation tissue (score 2) (B), peripherally and centrally present newly blood vessels (angiogenesis) (score 2), (C), without inflammatory infiltration (score 0) and irregular full thickness of reepithelialization of the wound area (score 3) (D).400X.

On Two independent Sample (Mann-Whitney U test), the statistical test showed that the mean of melatonin treated group is higher than of control group for inflammation, granulation and reepithelization, at

P-value ≤ 0.05 which indicate there is a significant difference in inflammation, granulation and reepithelization between two groups while P-value of angiogenesis was found to be more than 0.05 which indicate a non-significant difference between melatonin and control group.

DISCUSSION

The natural wound healing process is a primary goal of every surgical procedure (Yeyen *et al.*, 2013). Wound healing is a multi-step process that begins with the inflammation and progresses through granulation tissue formation, angiogenesis, re-epithelization, and wound contraction (Taqa *et al.*, 2014).

In this research, we found that melatonin accelerates wound healing after tooth extraction in rabbits; these results agree with the previous study that shows melatonin accelerates normal wound healing in rats by interacting with and modulating key biological processes such as inflammation, angiogenesis, collagen synthesis, and scar formation that drive the wound healing response (Pugazhenthir *et al.*, 2008).

This project showed a decline in the inflammatory response in groups treated with systemic melatonin. This agreement with Xu *et al.*, (2020) who reported that melatonin is a bioactive substance that can effectively promote muscle recovery by inhibiting oxidative stress and inflammation.

Acute inflammation and chronic inflammation stages occur during the inflammation stage, and Macrophages are cells that actively contribute during the chronic inflammation stage. Macrophages perform phagocytosis, collagen synthesis, granulation tissue creation in cooperation with fibroblasts, growth factor generation, and angiogenesis (the formation of new capillaries) (Yulilati *et al.*, 2020). According to Mei *et al.*, (2002) that showed melatonin could regulate macrophage activity.

This study shows that the positive effect of melatonin on angiogenesis in the socket is supported and agreed with several studies like Soybilir *et al.*, (2003) who found that after applying melatonin to wounds, the number of vessels increased. Jin *et al.*, (2018) said that melatonin sped up the healing process in diabetic mice. Mice in diabetes with the melatonin group had more capillaries than those in the diabetes group (Chen *et al.*, 2021). Ma *et al.*, (2020) showed melatonin has a positive effect on both angiogenesis and wound healing. Melatonin therapy also accelerated the angiogenic process by raising vascular endothelial growth factor protein, which increased the development of new blood vessels (VEGF) which is a

major contributor to angiogenesis) expression during granulation tissue formation.

The current study's histopathological findings revealed significant variations in wound healing between control and melatonin-treated groups. using it increases the granulation tissue and reepithelialization and this agrees with **Kaczmarek-Szczepańska *et al.*, (2021)** that showed melatonin accelerates reepithelialization., On days 7 and 21. **Jin *et al.*, (2018)** revealed that the diabetes group treated with melatonin had more collagen deposition than the diabetes group. Melatonin therapy increased arginase activity (which produces proline, a component of collagen formation) from earlier periods (**Ma, *et al.*, 2020**).

Melatonin's ability to speed wound healing in this study may be due to its ability to reduce oxidative stress. It is thought to have a far more substantial antioxidant impact than vitamins E, C, and glutathione. This property aids wound healing, as compared to traditional antioxidants, which neutralize one or less ROS, the molecule can capture up to ten (**Tan *et al.*, 2015**).

CONCLUSION

This study showed that melatonin administration speeds up the healing process of the wound of a tooth socket. This is manifested by decreasing the inflammatory cells and increasing angiogenesis of blood vessels, granulation tissue formation, and reepithelization.

Declaration of Conflicting Interests

The authors revealed that there is no potential conflicts of interest.
