ABSTRACT

Endophthalmitis is one of the most devastating diagnoses in veterinary and human ophthalmology. Ocular ultrasound is an effective and non-invasive technique used for evaluating the structures of the eye and the surrounding tissues, especially when the development of ocular opacities in conditions such as corneal disease, uveitis, cataracts or trauma prevent or limit the use of ophthalmoscopy and slit-lamp biomicroscopy. The present study aimed to evaluate the ultrasonographic characteristics of endophthalmitis in cats and to assess the usefulness of ultrasonography in the selection of treatment methods in such cases. Sixty cats (90 eyes) of different breeds were presented with bilateral (30 cats) and unilateral (30 cats; OD=10, OS=20) endophthalmitis. The mean age $\pm$ SEM at the initial presentation was 13.46 ± 1.69 months (range, 2 - 72 months). After a thorough ophthalmic examination, the ultrasonographic evaluation using a high frequency (7.5-10 MHz) micro-convex probe was conducted to evaluate the concurrent ocular abnormalities in the anterior and posterior eye segments. After completing the ultrasonographic examination, the treatment protocol was applied. It was concluded that ocular ultrasonographic evaluation was found suitable in the diagnosis of endophthalmitis in cats and for the selection of the treatment protocol.

Keywords: Cat, Endophthalmitis, retinal detachment, ultrasonography, vitreous detachment.

INTRODUCTION

Endophthalmitis is a serious intraocular inflammatory disorder affecting the vitreous cavity that can result from the exogenous or endogenous spread of infecting organisms into the eye (Esson, 2015). The disease is common in cats following corneal perforation after cat claw injury (Spiess *et al.*, 1996) and from the progression of a deep or melting corneal ulcer (Brooks and Matthews, 2007). Symptoms can be variable, from very little inflammation in the anterior chamber and the anterior portion of the vitreous to extremely painful panophthalmitis with no fundus view, corneal edema, or complete anterior chamber hypopyon (Mamalis *et al.*, 2002).

Ocular ultrasound is an effective and non-invasive technique used to evaluate the eyeball structures and the surrounding tissues (Fielding, 2001). The technique is useful for diagnosing the internal structures of the eye especially when the development

of ocular opacities in conditions such as corneal disease, uveitis, cataracts or trauma prevent or limit the use of ophthalmoscopy and slit-lamp biomicroscopy (Scotty *et al.*, 2004 and Mackay and Mattoon, 2015). Ocular ultrasonography allows for the evaluation of structures such as the cornea, anterior chamber, iris, ciliary body, lens, vitreous chamber and the posterior section of the bulbar wall (Nautrup, Tobias, 2000 and Singh *et al.*, 2015). Reviewing the veterinary literature, ocular ultrasonography was utilized for evaluation of the ocular abnormalities in dogs (Daret *et al.*, 2014), Buffaloes (Singh *et al.*, 2016) and in horses (Gialletti *et al.*, 2018). In human ophthalmology, many previous literatures have been evaluated ultrasonography in the diagnosis of different ocular diseases and the utility of ocular ultrasonography in diagnosing endophthalmitis was fully described (Marchini *et al.*, 1995 and Kohanim, 2012). For author knowledge, no previous studies were used to evaluate ultrasonographic abnormalities associated with endophthalmitis in cats except for one case report (Guyonnet *et al.*, 2019).

Therefore, the present study aimed to evaluate the ultrasonographic characteristics of ocular abnormalities associated with endophthalmitis in cats and to assess the usefulness of ultrasonography in the selection of the treatment method in such clinical cases.

MATERIALS AND METHODS

Animals

The present study was carried out on sixty pet cats (90 affected eyes) of different breeds and of both sexes. The enrolled cats were examined by the ophthalmology service at the Department of Surgery, Anesthesiology and Radiology, Faculty of Veterinary Medicine, Cairo University, Egypt. Cat's owners were aware that their cats will be used for research purposes and signed a consent indicating their approval. Data collected included signalment, history, duration of clinical signs and ophthalmic examination abnormalities. After complete ophthalmic examination, the inclusion criteria included cats diagnosed with endophthalmitis secondary to hyper mature cataract (phacoanaphylactic endophthalmitis) and buphthalmos iridocyclitis, posterior segment abnormalities or perforating corneal injury.

Ultrasonographic examination

Prior to ultrasonographic scanning, topical corneal anesthesia was achieved via the installation of benoxate hydrochloride 0.4% (**Douet et al., 2013**) (Benox®; EIPICO, Cairo, Egypt). Then highly purified ultrasound gel (Parker Aquasonic 100®, UK) was applied over the eye to be scanned (**Mackay and Mattoon, 2015**). The cats were restrained in sternal recumbency with head fixated for ultrasonographic scanning. Ultrasonographic scanning was performed gently using a 7.5-10 MHz micro-convex probe (EDAN DUS 60 PRO, digital ultrasound, Shenzhen, PR China) as described by (**Featherstone and Heinrich, 2013 and Mackay and Mattoon, 2015**). The ultrasonographic evaluation was carried out by systematically examining the cornea, anterior chamber, lens, iris and ciliary body, vitreous humor, ocular fundus, and retro-bulbar space.

Various scanning planes were used including trans-corneal (axial), trans-scleral and tangential approaches. For general screening, the axial approach or scanning along the central optic axis was used in a transverse and sagittal plane. The trans-scleral approach, which is scanning through the lens, is avoided and used for imaging structures in the posterior segment. In the tangential approach, the transducer was applied against the cornea for better visualization of the anterior structures (**Schmid, 2007**).

RESULTS

Animals

The breeds included in the present study were Domestic shorthair (DSH, $n = 30$), Persian ($n = 20$), Himalayan ($n = 5$), and Siamese ($n = 5$). The mean age $\pm$ SEM at the initial presentation was 13.46 ± 1.69 months (range, 2 - 72 months). There were 45 males (30 intact and 15 castrated) and 15 intact females. The mean $\pm$ SEM duration of clinical signs prior to presentation was 9.76 ± 0.78 days (range, 2 - 28 days). Both eyes were involved in 30 (50%) cats, the left eye (OS; Oculus Sinister) was affected in 20 (33.33%) cats and the right eye (OD; Oculus Dexter) was involved in 10 (16.66%) cats.

Ophthalmic and ultrasonographic findings

Based on concurrent ocular abnormalities, the cases of endophthalmitis were categorized into: corneal perforation with keratocoele/or large protruding fibrin clot over the corneal surface, buphthalmos, phacoanaphylactic endophthalmitis and iridocyclitis.

Unresponsive endophthalmitis secondary to corneal perforation was diagnosed in 40 eyes (40/90; 44.44%). The cause of corneal perforation was non-traumatic as a progression of deep stromal or melting ulcer in 23 (23/40; 57.5%) eyes and was traumatic as a result of cat claw injury in 17 (17/40; 42.5%) eyes. The clinical presentation included corneal vascularization, edema and large protruded fibrin clot over the corneal surface (Figure 1a), corneal melting (Figure 1b), hyphema (Figure 1c) and conjunctival chemosis, keratocoele and collapsed anterior chamber (Figure 1d). The ultrasonographic evaluation revealed intraocular hemorrhage in 20 (20/40; 50%) eyes, pus inside the eyeball in 10 (10/40; 25%) eyes and low-reflectivity endovitreous echoes in 10 (10/40; 25%) eyes.

Intraocular bleeding appeared as amorphous opacities to hypoechoic patchy zones filling the anterior and posterior chamber (Figure 2a) in 8 (8/20; 40%) eyes and was associated with the thick hyperechoic retina and optic nerve (Figure 2b and c) in 12 (12/20; 60%) eyes. A vitreous detachment was seen in 7 (7/20; 35%) eyes with vitreous bleeding.

The pus appeared as hypoechoic fluid filling the eyeball, which was settled at the bottom due to gravity leaving anechoic space behind the posterior lens capsule (Figure 2d). The retina appeared as a thick hyperechoic membrane under the settled hypoechoic fluid. The lens capsule appeared as incomplete hyperechoic lines indicating early cataractous changes. Based on the ultrasonographic evaluation, eye exenteration was performed in these cases.

The conducted treatment protocol for eyes with corneal perforation and ultrasonographic appearance of low-reflectivity endovitreous echoes was conjunctival pedicle flap technique and systemic course of antibiotic ceftriaxone (ceftriaxone®, Sandoz, Egypt) at a dose of 25mg/ kg i.m for seven days. Moxifloxacin hydrochloride 0.5% (Vigamox®, Alcon, Egypt) and diclofenac sodium 0.1% (Epifenac®, EIPICO, Egypt) were used to control postoperative infection, pain and discomfort. Based on clinical and ultrasonographic characteristics of the eyes with corneal perforation and secondary optic neuritis, retinitis, vitreous hemorrhage/or detachment, eye evisceration and ocular prostheses using silicone oil combined with conjunctival pedicle flap were the selected methods of treatment (Figure 2e).

Buphthalmos and chronic glaucoma were diagnosed in 25(25/90; 27.77%) eyes. Eighteen eyes (18/25; 72%) showed diffuse corneal edema and vascularization (Figure 3a), five eyes (5/25;20%) showed corneal edema, corneal vascularization and anterior synechia with a pupillary block (Figure 3b) and two eyes (2/25;8%) were presented with corneal abscessation and granulation tissue (Figure 3c) and corneal ulceration, pigmentation and vascularization (Figure 3d).

The ultrasonographic evaluation revealed an enlarged and misshapen globe (Figure 4a-d) in all cases with buphthalmos. Retinal detachment was observed in all eyes with buphthalmos was associated with a vitreous detachment in 20 eyes (20/25;80%). The type of retinal detachment recorded in these cases was mainly exudative and was shown as thick echogenic membrane/s that followed up to the optic nerve. The sub-retinal space appeared anechoic with floating hypoechoic dots (Figure 4b, c and d). In the cases with vitreous detachment, a hypoechoic membrane was formed leaving anechoic retro-vitreous space and was less echogenic than detached retinal membranes (Figure 4c and d). Numerous mobile vitreal echoes of variable amplitude were also observed. Based on the ultrasonographic findings, all cases with buphthalmos were treated by the exenteration of the eyeball.

Phacoanaphylactic endophthalmitis was diagnosed in 15 (15/90; 16.66%) eyes. All cases were presented with a hyper mature cataract. The cataractous lens was secondarily luxated in 8 (8/15; 53.33%) eyes anteriorly, partially luxated in 4(4/15; 26.66%) eyes and posteriorly luxated in 3 (3/15; 20%) eyes. All cases of anterior lens-luxation were associated with secondary glaucoma. The ultrasonographic evaluation revealed that the cataractous dislocated lens was

associated with endophthalmitis and enlargement of the globe (Figure 5a), vitreous detachment and hyperechoic floating dots were also seen inside the vitreous (Figure 5b). Posteriorly luxated lenses were well-visualized inside the vitreous (Figure 5c). Cases with partially dislocated lenses showed characteristic aphakic crescent and iris atrophy (Figure 5d) and the ultrasonographic pictures revealed vitreous detachment, hyperechoic floating dots and thickened iris tissue (Figure 5e).

The anteriorly dislocated lenses were removed via intra-capsular lens extraction (Figure 5f). The eyes with partial and posterior lens-luxation received only medical treatment in the form of topical eye drops every 8 to 12 hours for 14 days; tobramycin/dexamethasone combination (Tobradex®; Alcon, Egypt) and pilocarpine hydrochloride 2% (Isoptocarpine® 2%, Alcon, Egypt). The treatment was applied to keep the lens in position and to minimize intraocular inflammation.

Iridocyclitis was diagnosed in 10 (10/90; 11.11%) eyes and the recorded clinical findings were corneal edema, miosis, ciliary injection, conjunctival chemosis and episcleral injection. Secondary cataract and anterior synechia were seen in 3 (3/10; 30%) eyes and glaucoma (angle-closure glaucoma) was diagnosed in 2 (2/10; 20%) eyes.

In Five animals (5/10; 50%) eyes, ultrasonographic examination revealed thickening and increased echogenicity of the ciliary body, iris tissue, globe wall and hyperechoic optic nerve with early cataractous changes (Figure 6a and b). The conducted treatment protocol for these cats included systemic dexamethasone sodium phosphate (Dexamethasone® 4mg, Amriya Pharma IND, Egypt) 0.1mg/kg IV at three days interval/ 4 injections and topical eye drops every 8 to 12 hours for 14 days; tobramycin/dexamethasone combination and tropicamide 1% (Mydriacyl®, Alcon, Egypt).

Anterior synechia (Figure 6c), iris bombe (Figure 6d) and pupillary block glaucoma (Figure 6e) were diagnosed in 5 eyes out of 10 with iridocyclitis. Iridotomy was performed in three cats with iris bombe and two cats with pupillary block glaucoma. Clinical findings, ultrasonographic characteristics and treatment protocols of 60 cats (90 eyes) with endophthalmitis were summarized in Table 2.

Figure 1: The clinical presentation of endophthalmitis secondary to corneal perforation. (a) Corneal vascularization, edema and large protruding fibrin clot sealing the corneal defect in 36 months-old Persian cats, (b) Corneal melting in 24 months-old DSH cat, (c) Cat claw injury with keratocoele, hyphema and corneal edema in 72 months-old DSH cat and (d) Conjunctival chemosis, keratocoele and collapsed anterior chamber in 18-months old DSH cat.

Figure 2: Trans-corneal (a), trans-scleral (b and c) ultrasonographic scans of the eyes with endophthalmitis secondary to corneal perforation showing vitreal hemorrhage (H), hyperechoic thickened globe wall (red arrow), thickened retina (R), vitreal detachment (yellow arrow), thickened optic nerve (ON) with surrounding anechoic space (blue arrow) filled with hypoechoic dots (black arrow). (d) Axial ultrasonographic scan showing pus (P) in the anterior and posterior chamber with anechoic space under the lens (white arrow), early cataractous changes (red arrow) and thickened retina (yellow arrow). (e) Ocular prostheses with silicone oil (SO) filling the eviscerated eyeball.

Figure 3: the clinical presentation of buphthalmos with diffuse corneal edema and vascularization (a), pupillary block glaucoma (b), corneal abscessation and granulation tissue (c) and corneal ulceration and pigmentation (d).

Figure 4: Trans-scleral ultrasonographic images showing enlarged misshapen globe (a-d), echogenic endovitreous echoes (white arrow), detached retina (R) retinal folds (red arrow), detached vitreous (V) and anechoic subretinal space filled with hypoechoic dots (yellow arrow).

Figure 5: Trans-corneal ultrasonographic views showing anterior (a and b) and posterior (c) luxation of the cataractous lens (L), thickened iris (i), vitreal detachment (red arrow), vitreal hemorrhage (H) and echogenic endovitreal dots (white arrow). (c) Partially luxated lens with clear aphakic crescent and iris atrophy. (d) Ultrasonographic image showing the phacoanaphylactic endophthalmitis accompanied the eyes with hyper mature cataract and partial lens luxation. (f) The eye of a Persian cat after successful lens extraction

Figure 6: Trans-corneal views (a and b) of iridocyclitis and secondary endophthalmitis showing thickened ciliary body (Cb), iris (i), early cataractous changes (yellow arrow), retinal folds (red arrow) and vitreal hemorrhage (H). (c) Tangential view showing anterior synechia. (d) Iris bombe and echogenic cataractous lens with a deep anterior chamber (plus sign). (e) Tangential view showing pupillary block glaucoma and deep anterior chamber (plus sign).

Table 1. Clinical findings, ultrasonographic characteristics of 60 cats with endophthalmitis

Cause endophthalmitis	Affected eye (No. of cats)	Clinical findings	Ultrasonographic findings
Corneal perforation (30 cats)	Both (5 cats) OS (2 cats) OD (1 cat)	Corneal melting, Corneal vascularization, Corneal edema	Endovitreous hypoechoic patchy zones, Hyperechoic thickened retina and thickened hyperechoic optic nerve
	Both (5 cats)	Deep stromal ulcer, Keratocoele, Corneal edema, Corneal vascularization	Low-reflectivity endovitreous echoes
	OD (4 cats) OS (3 cats)	Cat claw injury, Corneal edema, Corneal vascularization, Cornea defect sealed with fibrin clot, Hyphema	Endovitreous amorphous to hypoechoic patchy zones, Hyperechoic thickened retina and endovitreous membranes
	OS (6 cats) OD (4 cats)	Cat claw injury, Corneal perforation, Large protruding fibrin clot over the cornea defect, Corneal edema, Corneal vascularization	Homogeneously non-movable hypoechoic patchy zone filling the eye ball (pus), Thickened hyperechoic retina
Buphthalmos (15 cats)	Both (9 cats)	Unresponsive glaucoma, Diffuse corneal edema, Corneal vascularization	Misshapen globe, Thin globe wall, Exudative retinal detachment, Vitreous detachment
	OS (5 cats)	Unresponsive glaucoma, Corneal edema, corneal vascularization and anterior synechia	Misshapen globe. Exudative retinal detachment
	Both (1 cat)	Unresponsive glaucoma, Corneal ulceration, Corneal pigmentation, Corneal vascularization, Corneal abscessation	Misshapen globe, Exudative retinal detachment, Vitreous detachment
Phacoanaphylactic endophthalmitis (9 cats)	Both (4 cats)	Hyperacute cataract, Anteriorly luxated, cataractous lens, Secondary glaucoma	Low-reflectivity endovitreous echoes, Vitreous detachment
	OS (3 cats)	Hyperacute cataract, Posteriorly luxated, cataractous lens	Low-reflectivity endovitreous echoes
	Both (2 cats)	Hyperacute cataract, partially luxated lens, iris atrophy and aphakic crescent	Low-reflectivity endovitreous echoes, Vitreal hemorrhage
Iridocyclitis (6 cats)	Both (2 cats) OD (1 cat)	Corneal edema, miosis, ciliary injection and conjunctival chemosis	Thickening of the iris, Thickened hyperechoic ciliary body
	Both (1 cat) OS (1 cat)	Secondary cataract, iris bombe	Anterior synechia, Hypoechoic lens
	Both (1 cat)	Pupillary-block glaucoma, corneal edema and episcleral injection	Thickening of the iris, Low-reflectivity endovitreous echoes

OD; Oculus Dexter, OS; Oculus Sinister

Table 2. The treatment protocol conducted for sixty cats (90 eyes) with endophthalmitis

Cause of endophthalmitis	Number of eyes (%)	Associated findings	Treatment
Corneal perforation (40 eyes)	13 (32.5%)	Corneal melting	Eye evisceration and ocular prostheses
	10 (25%)	Deep stromal ulcer	Conjunctival pedicle flap
	7 (17.5 %)	Cat claw injury	Eye evisceration and ocular prosthesis
	10 (25%)	Cat claw injury with pus inside the eyeball	Eye exenteration
Buphthalmos (25 eyes)	25 (100%)	Unresponsive glaucoma	Eye exenteration
Phacoanaphylactic endophthalmitis (15 eyes)	8 (53.33%)	Anteriorly luxated lens	Intracapsular lens extraction
	4 (26.66%)	Posteriorly luxated lens	Miotics, Topical corticosteroids
	3 (20%)	Partially luxated lens	Miotics, Topical corticosteroids
Iridocyclitis (10 eyes)	5 (50%)	-	Corticosteroids Mydriatics
	3 (30%)	Iris bombe, cataract	Iridotomy, Corticosteroids, ydriatics
	2 (20%)	Pupillary block glaucoma	Iridotomy, Corticosteroids

DISCUSSION

Endophthalmitis is commonly seen in the veterinary patients in the course of a corneal ulcer (Brooks and Matthews, 2007) or as a perforating eye injury (Spiess *et al.*, 1996). Clinical diagnosis of endophthalmitis is based on major signs of inflammation in the anterior segment of the eyeball. However, incomplete visualization of the eye due to the development of ocular opacities limits the use of ophthalmoscopy and slit-lamp biomicroscopy (Scotty *et al.*, 2004 and Mackay and Mattoon, 2015). In these cases, ultrasonography may prove useful for determining the severity and extent of ocular involvement. Furthermore, no studies have correlated the ultrasonographic characteristics of endophthalmitis in cats to the selected treatment protocol.

The present study documented various types of ocular abnormalities in the course of endophthalmitis in cats. In addition, the correlation between the clinical and ultrasonographic findings was also reported and the treatment protocol for every condition was conducted.

In this study, trans-corneal scanning provided reliable images of the posterior segment of the globe

(Mackay and Mattoon, 2015 and Singh *et al.*, 2015) and imaging through the eyelid was avoided to limit artifacts or image degradation. The used high transducer frequencies (7.5–10 MHz) allowed for superior resolution of the posterior segment with focal zones of 2–5 cm (Williams and Wilkie, 1996). Moreover, the used tangential approach and trans-scleral approach were useful for visualization of the anterior structures and posterior structures, respectively (Schmid, 2007).

The chronic leakage, prolonged hypotony and a collapsed anterior chamber after perforating ocular injuries contribute to endophthalmitis and severe intraocular hemorrhage (Mancuso *et al.*, 2016). In viewing the present study results, endophthalmitis was secondary to corneal perforation in 40 eyes (44.44%). Numerous ultrasonographic features have been reported including; intraocular hemorrhage in 20 (50%) eyes, pus inside the eyeball in 10 (25%) eyes and low-reflectivity endovitreous echoes in 10 (25%) eyes. The recorded endovitreous echoes were attributed to the infiltration, invasion and agglomeration of inflammatory cells inside the vitreous compartment (Schmid, 2007). Intraocular hemorrhage appeared as amorphous opacities to hypoechoic patchy zones filling the anterior and posterior chamber. The heterogeneous

echogenicity was attributed to the organization of the vitreal bleeding (Wilke and Gilger, 1998 and Schmid, 2007). A vitreous detachment was seen in 7 (7/20; 35%) eyes with vitreous bleeding and was characterized by anechoic retrovitreal space (Schmid, 2007).

A poor prognosis for vision is associated with vitreal hemorrhage (Cho *et al.*, 1998) because of the development of tractional retinal detachment, posterior synechia (Morgan, 1982), peripheral anterior synechia, secondary glaucoma, cataract formation (Nelms *et al.*, 1993) and phthisis bulbi (Crouch and Crouch, 1999). Regarding the results of the present study, the ultrasonographic examination of 20 eyes after corneal perforation revealed well-organized vitreal bleeding filling the whole vitreous compartment associated with the thick hyperechoic retina and optic nerve in 12 (60%) eyes and vitreous detachment in 7 (35%) eyes. These eyes were not potential for vision and the conducted treatment protocol was eye evisceration combined with intraocular prostheses, as required by the owners. The ocular contents were eviscerated through the trans-corneal approach and the silicone oil (Peña *et al.*, 1997) was then injected inside the globe to match the size of the opposite eye. A conjunctival pedicle flap technique was applied to close the corneal defect. After removal of the conjunctival flap, these cats responded extremely well with an attractive-ocular appearance.

However, the ultrasonographic examination of 10 eyes with corneal perforation due to cat claw injury revealed the presence of a homogeneously non-movable hypoechoic patchy zone filling the eyeball (pus) with the thickened hyperechoic retina. In these eyes, ocular prostheses were not performed because of the intraocular infection and eye exenteration was the conducted method of treatment (Miller, 2008a).

Buphthalmos and endophthalmitis secondary chronic untreatable glaucoma were recorded in 25 (27.77%) eyes. The associated clinical findings were diffuse corneal edema, anterior synechia with pupillary block and corneal abscessation with corneal granulation tissue. All these findings necessitated the use of ultrasonography to evaluate the internal structures of the eyeball. All cases of buphthalmos were associated with a retinal detachment associated with a vitreous detachment in 20 eyes (80%). However, the type of the retinal detachment was mainly exudative due to the extensive intra-ocular inflammatory process, which was proven by the presence of floating hypoechoic dots in the sub-retinal space (Schmid, 2007). The detached retina membranes appeared as diffuse thick echogenic membranes that

followed up to the optic nerve. This was in agreement with (McLeod *et al.*, 1977), who described the detached retina as a regular continuous sheet of high-amplitude echoes. The retina is usually attached firmly to the points of the ora serrata anteriorly and the optic nerve head posteriorly. The exenteration of the eyeball was performed in all eyes with buphthalmos based on the clinical and ultrasonographic appearance. Ocular prostheses were not performed to these cats due to the thin ocular wall and the misshapen enlarged globe.

Cataracts are degenerative changes that produce echogenicity at various locations within an anechoic lens. Cataract can be easily diagnosed from the clear clinical signs and leukocoria and by the aid of ophthalmoscopy and slit-lamp biomicroscopy (Gelatt and Mackay, 2005). However, echogenicity, size and shape of the lens may change with the type of cataract and its duration (Spaulding, 2008). Moreover, lens-induced uveitis, lens luxation and secondary glaucoma are common complications to hypermature cataract due to the phacoanaphylactic response to lens material (Collins and Moore, 1999). In addition, Lens-induced uveitis can be clinically evident or subclinical in cataractous patients (Gelatt and MacKay, 2005). In this study, ultrasonography was useful to diagnose the posterior segment involvement in cases with phacoanaphylactic endophthalmitis and lens luxation. The technique evaluated the position of the luxated lenses properly and the posterior segment findings were vitreous detachment and hyperechoic floating dots inside the vitreous chamber.

Regarding the results of the iridocyclitis, ultrasonography was practical in the selection of the appropriate method of treatment. Medicinal treatment was applied on five eyes to reduce the intraocular inflammatory process and to prevent possible complications. Surgical treatment was applied on five cats to correct the encountered complications as anterior synechia, iris bombe and secondary glaucoma (Miller, 2008b). Satisfactory results were obtained after treatment of all cats enrolled in this study with 1-3 months of observation and followed up. The recorded complications included mild to moderate degrees of corneal scarring (Ali and Hassan, 2020) in 5 eyes treated with conjunctival flap, persistent corneal edema in 2 eyes after intra-capsular lens extraction and in 3 eyes after iridotomy.

The most important limitation of the present study was the lack of histopathologic evidence to confirm the ultrasonographic diagnoses. Another limiting factor was the lack of correlation between the course of endophthalmitis and the ultrasonographic findings. Future studies should address both concerns.

CONCLUSIONS

In conclusion, the use of ultrasonography as an adjunct tool to assess the concurrent ocular abnormalities associated with different types of endophthalmitis in cats is very helpful in accurate diagnosis and for the selection of the treatment protocol.
